# Circumgalactic Medium

- Large reservoir of multiphase gas
- Fuel for star formation
- Massive (e.g., Werk 2013)
- MgII absorption in background QSO spectra
- Accretion along dark matter filaments
  - e.g., Rubin 2012
- Outflows from SN feedback/stellar winds
  - e.g., Bouche 2012
- Merging satellite galaxies
- Infalling and outflowing material preferentially found along major and minor axes (e.g., Bordoloi 2011, Kacprzak 2012, Lan 2014)

# MAGIICAT

- MgII Absorber-Galaxy Catalog
- Isolated galaxies have:
  - Detected MgII absorption or an upper limit on absorption
  - $D < 200$  kpc
  - Spectroscopic redshifts  $z < 1$
- Halo masses
  - Abundance matching
  - $10.7 < \log (M_h/M_{\text{sun}}) < 13.8$
  - Median  $\log (M_h/M_{\text{sun}}) = 12$

**Table 4**  
MAGnCAT Properties

Property	Min	Max	Median
$W_r(2796) (\text{\AA})$	0.003	4.422	0.400
$z_{\text{gal}}$	0.072	1.120	0.359
$D$ (kpc)	5.4	93.5	48.7
$M_B$	-16.1	23.1	-20.4
$M_K$	-17.0	25.3	-22.0
$L_B/L_B^*$	0.017	5.869	0.611
$L_K/L_K^*$	0.006	9.712	0.493
$B - K$	0.04	4.09	1.48

Paper III: Churchill+ 2013, ApJ, 779, 87  
Masses from halo abundance matching

# Kinematics Subsample

- 47 MAGIICAT absorber-galaxy pairs with HIRES/UVES spectra
- Voigt profile fitted
- Quantities obtained from fitting:
  - # of clouds and **cloud velocity**, EW, column density, & Doppler b parameter
- EW sensitivity cut of  $0.07 \text{ \AA}$

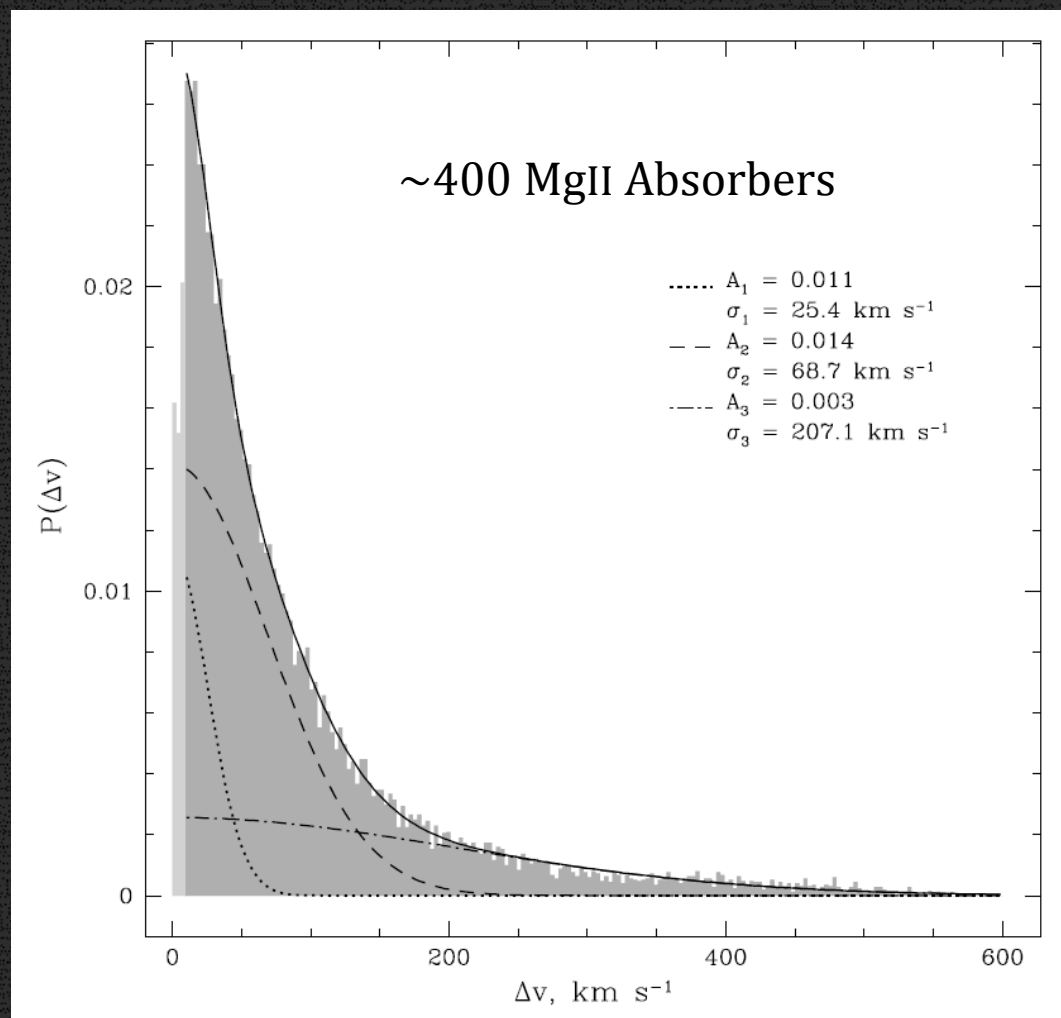

# Two-Point Velocity Correlation Function

- Cloud-cloud velocity probability distribution function
- Probability of finding any two clouds separated by  $\Delta v$

# Two-Point Velocity Correlation Function

Other works attribute  
gaussians to:

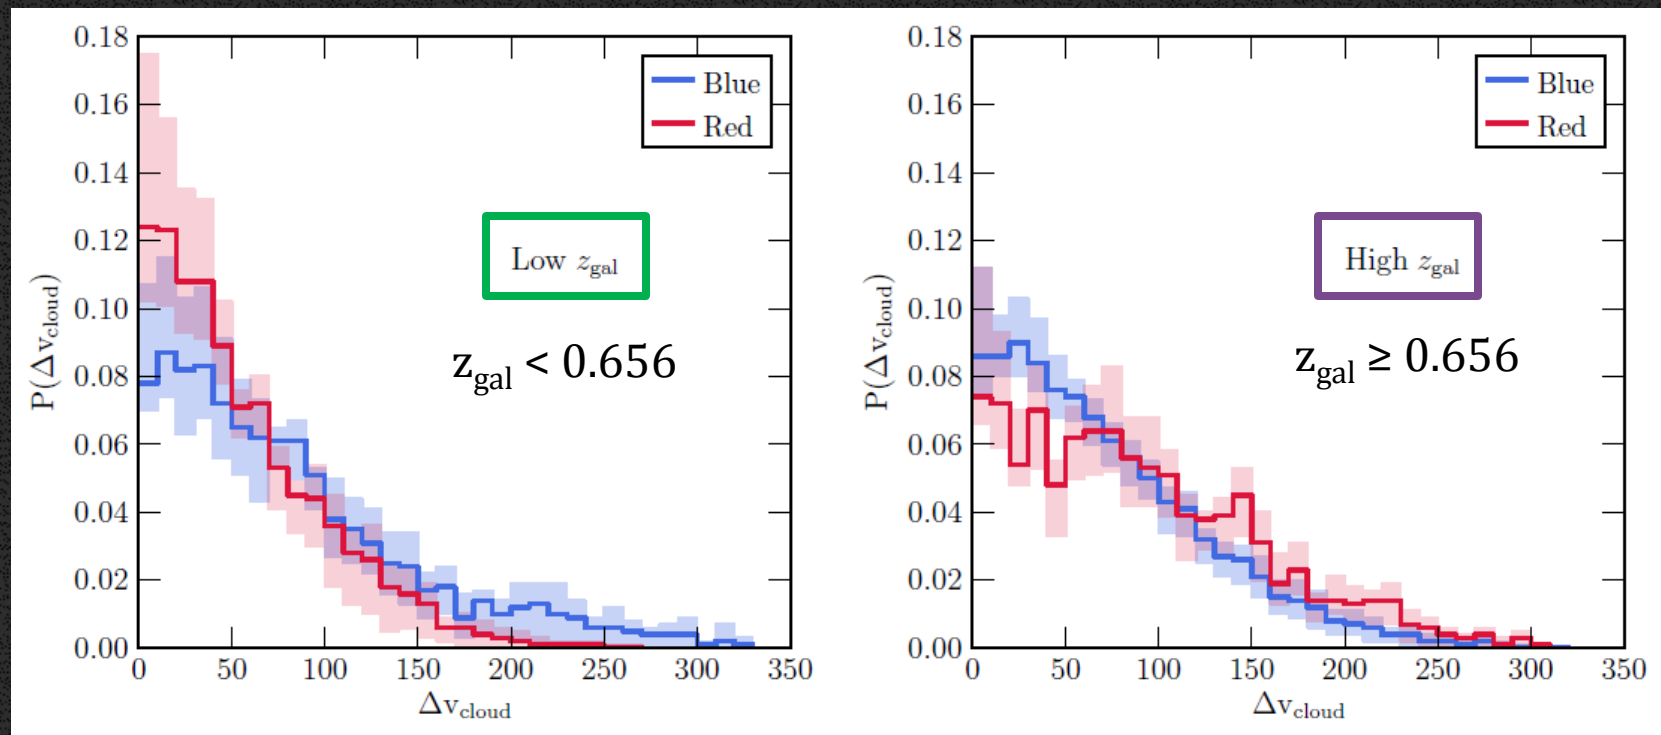

Motions within galaxy and  
between galaxy pairs  
(Petitjean & Bergeron 1990)

Vertical dispersion in galaxy  
disks and rotational motion  
(Churchill+ 2003)

# Absorption TPCF (velocities with respect to $z_{\text{abs}}$ )

- **Low  $z$ :** absorbers around red galaxies are more relaxed than blue
- **High  $z$ :** similar velocity structure

B-K cut = 1.4

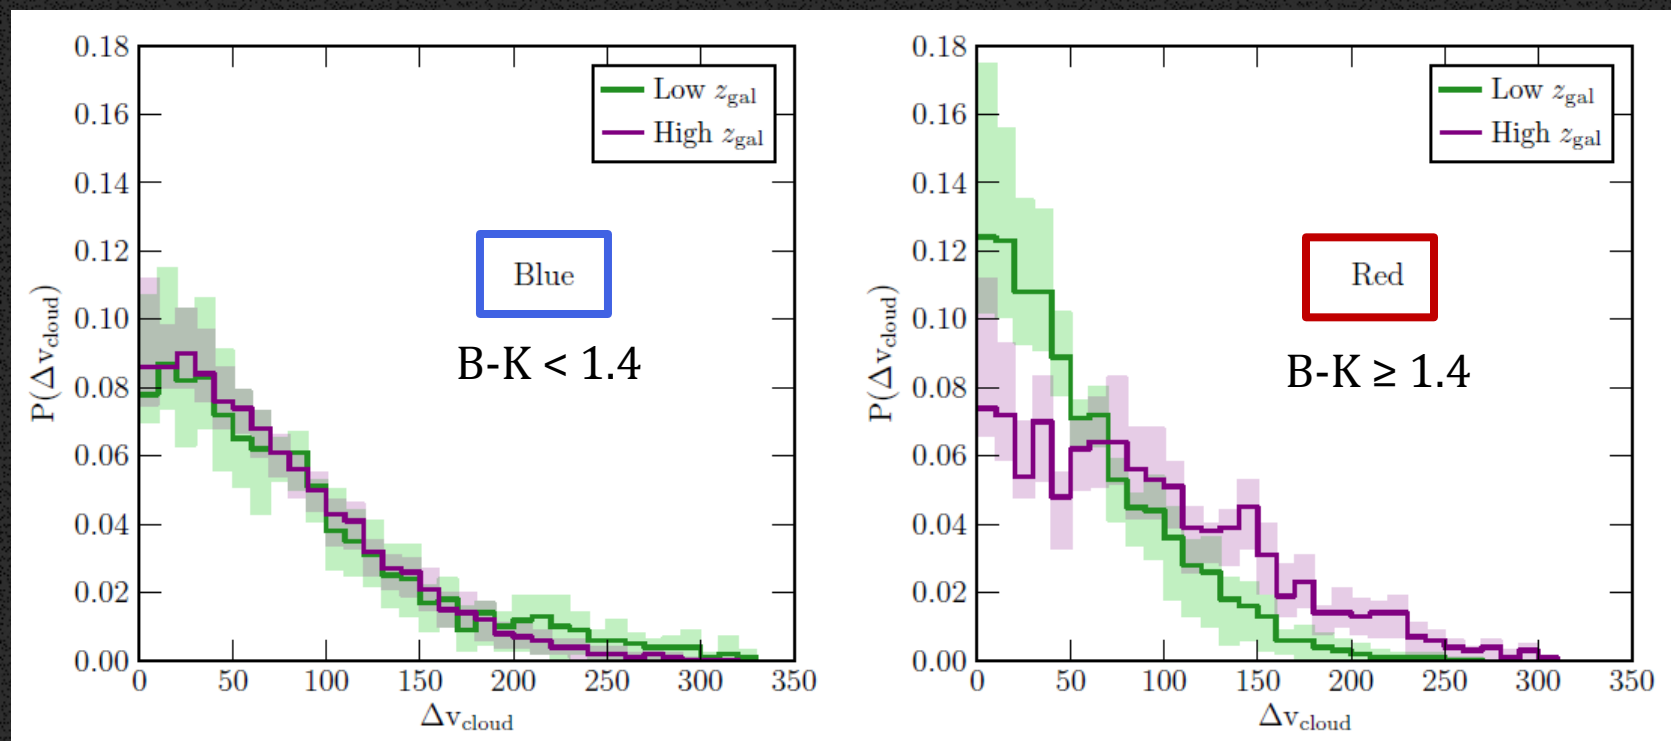

# Absorption TPCF (velocities with respect to $z_{\text{abs}}$ )

- Blue galaxies – velocity structure unchanged over 2 Gyrs;  $P(\text{KS})=0.0186$
- Red galaxies – redshift evolution with gas becoming more relaxed at low  $z$ ; absorbers less turbulent

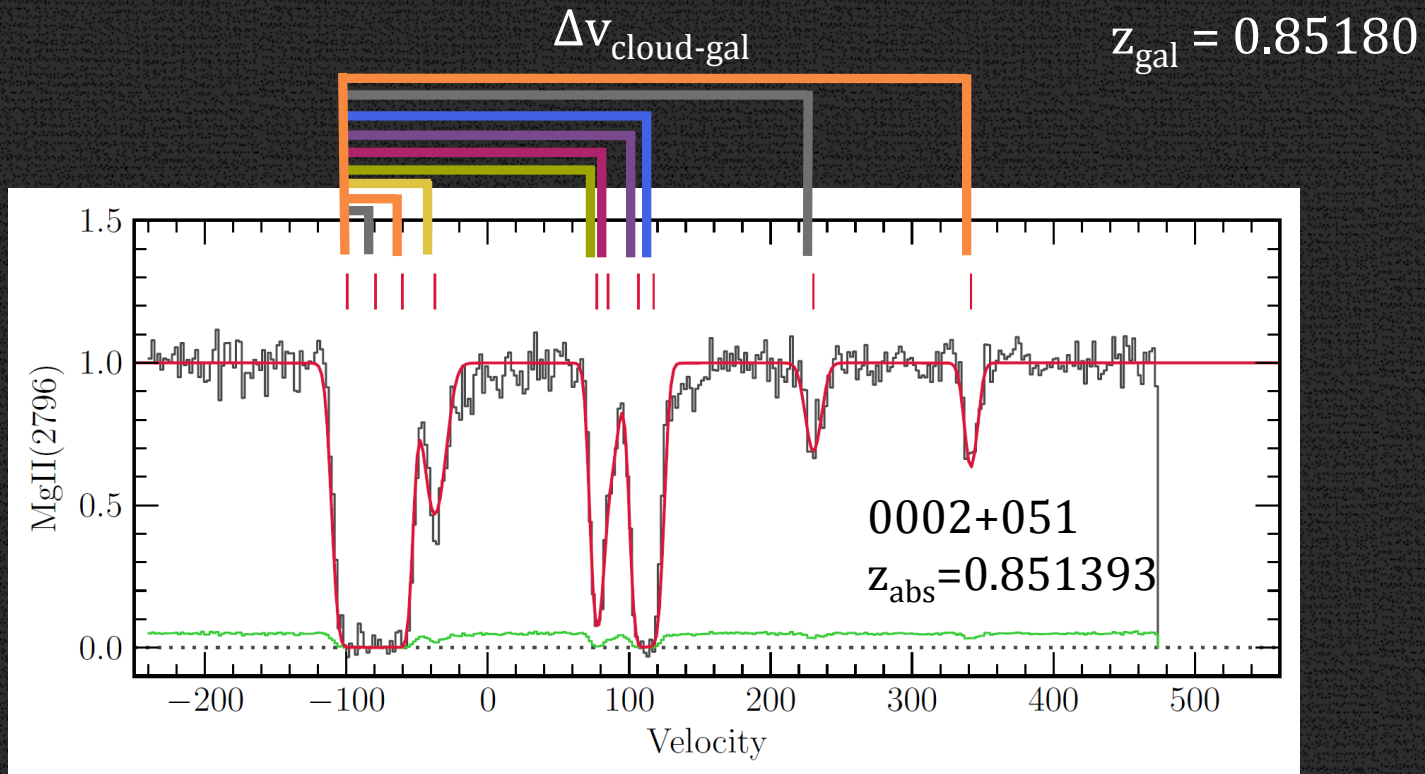

$z_{\text{gal}} \text{ cut} = 0.656$

# TPCF with respect to the galaxy

# TPCF with respect to the galaxy

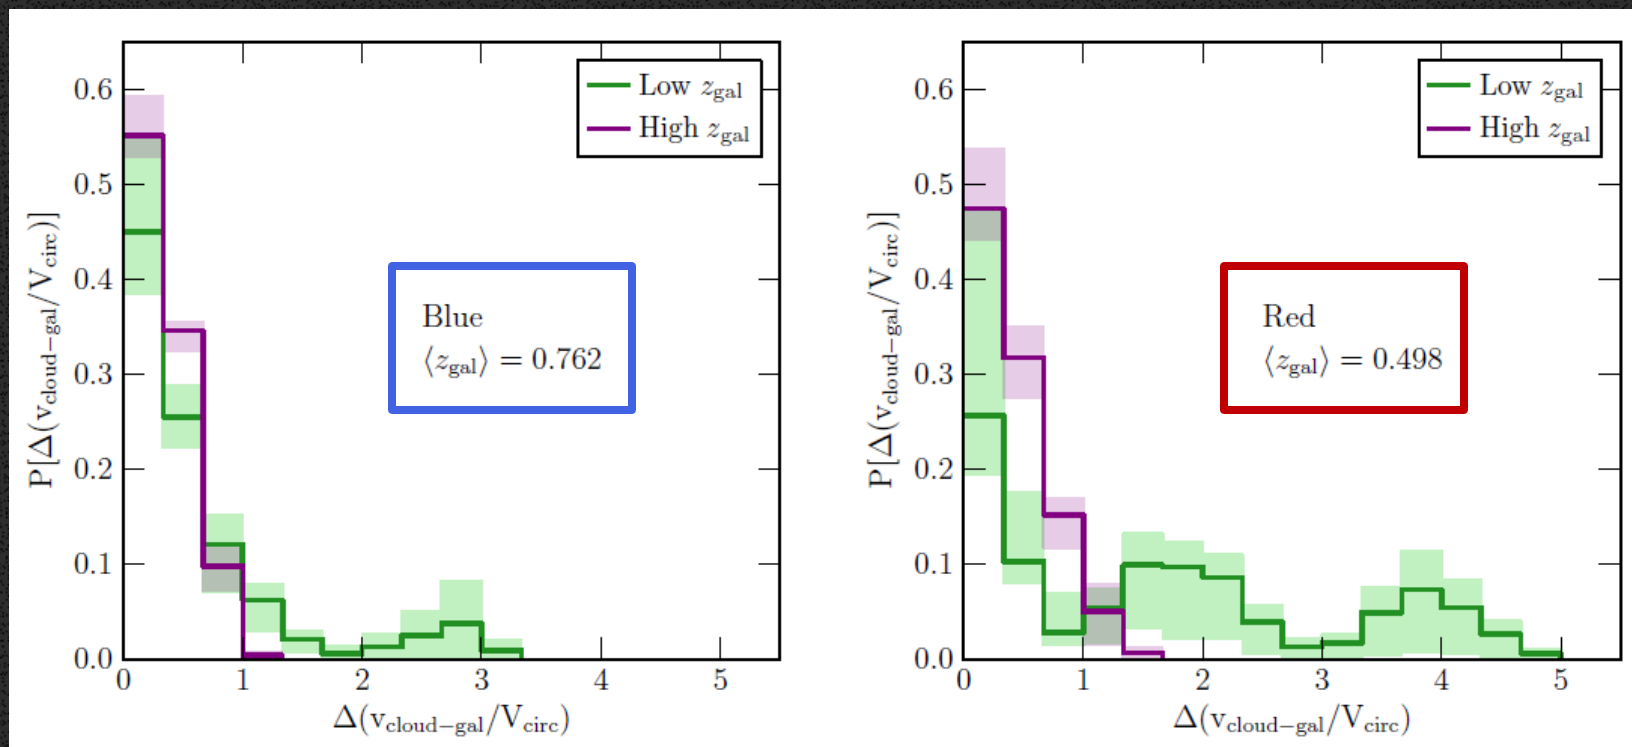

# TPCF normalized with respect to the galaxy

# TPCF normalized with respect to the galaxy

- Blue galaxies – narrow velocity range, possible winds at low  $z$
- Red galaxies – narrow velocity range at high  $z$ , high velocities at low  $z$ , more extended in velocity than blue gals

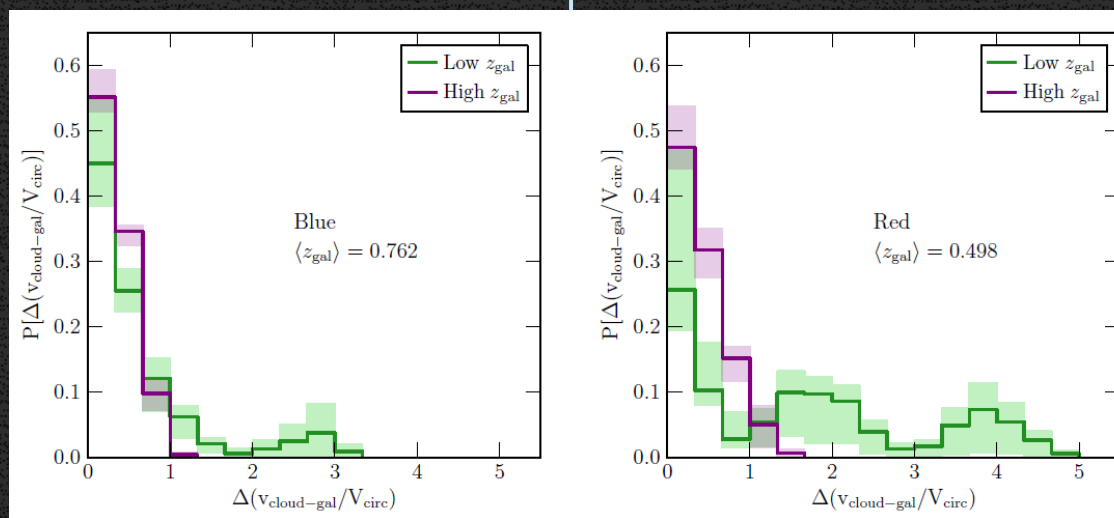

# Quandaries...

## Questions

- What is the kinematic nature of higher velocity material around galaxies at lower  $z$ ?
- Why is it present and so dramatic in red galaxies?

## Expectations

- Blue galaxies currently forming stars, red galaxies are not
  - Outflows and infall expected in blue galaxies but not in red
- Red galaxies tend to be in more overdense environments
  - Material seen at high  $\Delta v$  might be gas in satellites

# Quandaries...

## Questions

- Why does gas in absorbers become more quiescent over time in red galaxies but more stirred up with respect to the galaxy at lower redshift?
- Simulations would help!

Internal  
absorber  
dispersion

## Expectations

- Expect the galaxies to become more quiescent over time rather than more active
  - Ancient outflows in red galaxies stirred up material while absorbers themselves have since settled

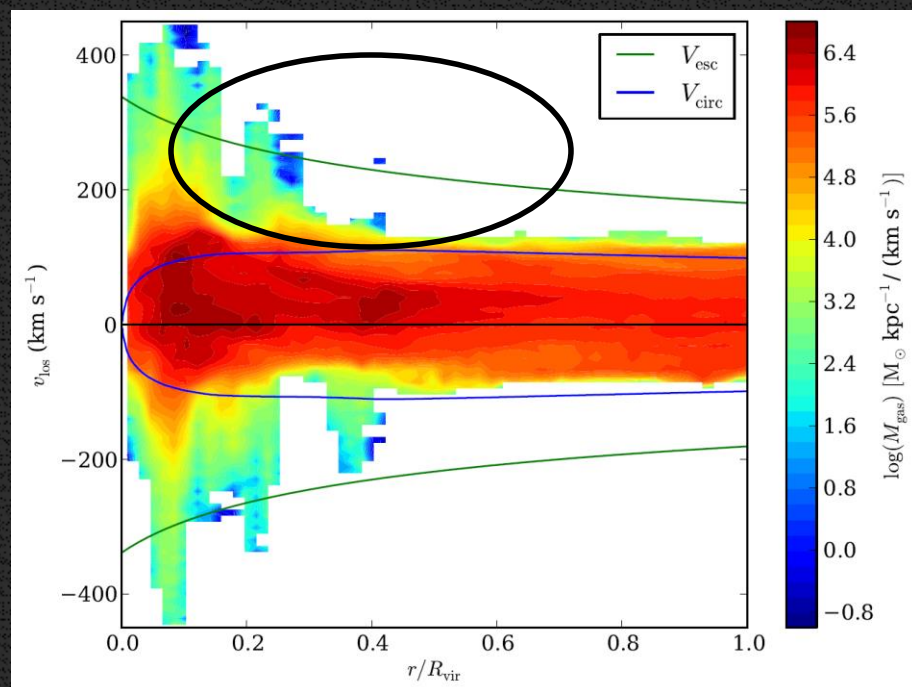

Dispersion  
of absorbers  
around  
galaxy

# Preliminary Simulation Results

- Adaptive mesh refinement N-body+hydrodynamics code *hydroART*
- Spiral galaxy model: spALL\_40;
- $\log M_h/M_{\text{sun}} = 11$

## Infalling material

## Outflowing material

# Conclusions

- Absorbers in red galaxies become more quiescent over time while blue galaxy absorber structures do not change over 2 Gyr
  - Absorption in blue galaxies may reflect ongoing evolution, while the settling of absorption in red galaxies may indicate passive evolution – no more stirring of the gas
- Absorption around galaxies at lower redshift has larger velocity dispersions than at higher redshift. Possible outflows at lower redshift?
  - This may indicate some dynamical mixing that could make it more difficult to accrete on the galaxy, especially for absorbers around red galaxies
- Preliminary simulations may indicate that material found with velocities exceeding  $V_{\text{circ}}$  are more likely to be outflowing
