From last class

Some astrochemistry jargon

Metal: anything that is not Hydrogen or Helium

The Astronomer's Periodic Table

From last class

Some astrochemistry jargon

Metal: anything that is not Hydrogen or Helium

X: Hydrogen abundance

Y: Helium abundance

Z: All the rest (i.e., abundance of metals)

$$X+Y+Z=1$$

Sun: $X=0.749$, $Y=0.238$, $Z=0.013$

Metallicity

Iron abundance (normalized to solar)

$$[Fe/H] = \log \left(\frac{N_{Fe}}{N_H} \right)_{\star} - \log \left(\frac{N_{Fe}}{N_H} \right)_{\odot}$$

Sun: $[Fe/H] = 0.0$

From last class

Some astrochemistry jargon

Successive generations of stars enrich the Galaxy in metals

From last class

From last class

Some astrochemistry jargon

Successive generations of stars enrich the Galaxy in metals

An age-metallicity relation can be traced

Age of the stars

From last class

Some astrochemistry jargon

Successive generations of stars enrich the Galaxy in metals

An age-metallicity relation can be traced

Stellar Populations

Population I

young and metal-rich

Population II

old and metal-poor

Age of the stars

From last class

Some astrochemistry jargon

Successive generations of stars enrich the Galaxy in metals

An age-metallicity relation can be traced

Stellar Populations

Pop I - Disk stars ; Pop II - Halo stars

Population II

old and metal-poor

Halo Stars

*Star formation
ceased long ago*

Population I

young and metal-rich

Disk Stars

*Star formation is
ongoing*

From last class

Some astrochemistry jargon

Successive generations of stars enrich the Galaxy in metals

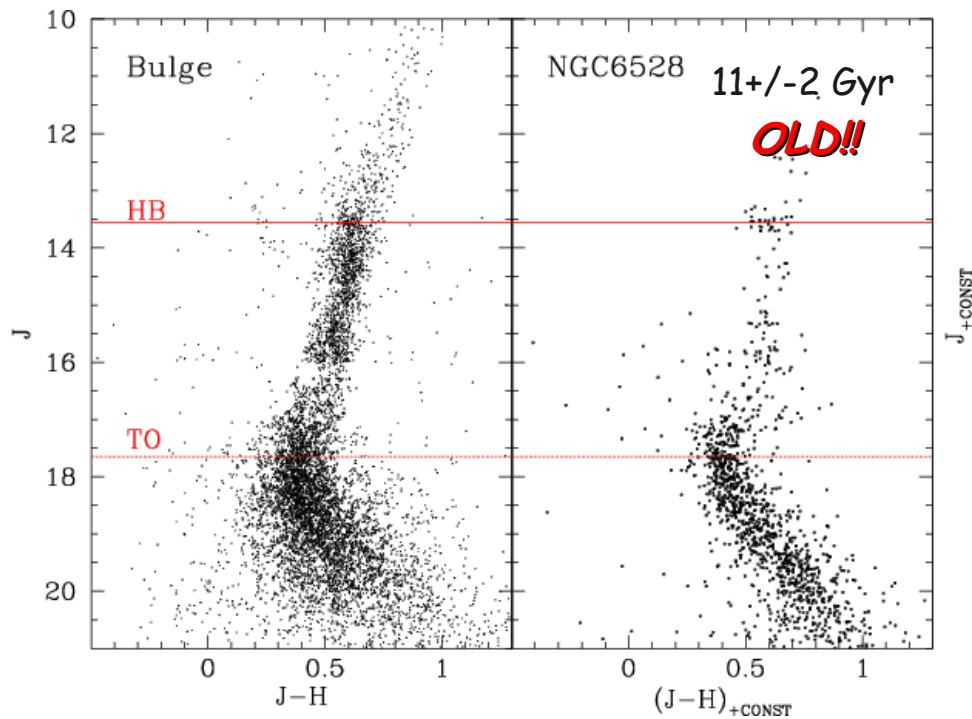

An age-metallicity relation can be traced

Stellar Populations

Pop I - Disk stars ; Pop II - Halo stars

Bulge stars break the classification. They are old and metal rich.

Age of the Bulge

Metallicity Distribution of the Bulge

From last class

Some astrochemistry jargon

Successive generations of stars enrich the Galaxy in metals

Star formation rate (SFR) is proportional to the density

An age-metallicity relation can be traced

Stellar Populations

Pop I - Disk stars ; Pop II - Halo stars

Bulge stars break the classification. They are old and metal rich.

That's because the bulge is dense. More gas, more stars. Fast chemical enrichment.

From last class

Some astrochemistry jargon

Successive generations of stars enrich the Galaxy in metals

Star formation rate (SFR) is proportional to the density

An age-metallicity relation can be traced

Central part (Bulge) → High gas density → Fast chemical enrichment

Outer disk → Low gas density → Slow chemical enrichment

Bulge stars break the classification. They are old and metal rich.

That's because the bulge is dense. More gas, more stars. Fast chemical enrichment.

The Galaxy has a radial metallicity gradient

From last class

Pop I – metal rich, young

Pop II – metal poor, old

Pop III – metal free, extinct

Population III stars - Metal free, the first stars

COSMIC TIMELINE

FROM THE DARK AGES ...

After the emission of the cosmic microwave background radiation (about 400,000 years after the big bang), the universe grew increasingly cold and dark. But cosmic structure gradually evolved from the density fluctuations left over from the big bang.

... TO THE RENAISSANCE

The appearance of the first stars and protogalaxies (perhaps as early as 100 million years after the big bang) set off a chain of events that transformed the universe.

The First Stars

Purely Hydrogen and Helium,
nothing else.

We cannot see them
since they are gone.

But... the **second** generation of stars
may still be around

From last class

Some astrochemistry jargon

Successive generations of stars enrich the Galaxy

An age-metallicity relation can be traced

Stellar Populations

Pop I - Disk stars ; Pop II - Halo stars

Bulge stars break the classification. They are old and

That's because the bulge is dense. More gas, more stars. Fast

The Galaxy has a radial metallicity gradient

Population III stars - Metal free, the first stars

HE 1327-2326: The most metal poor star ever found

[Fe/H] = -5.2

**300,000 times less Iron
than the Sun**

Outline

- Supernovae Types Ia and II
- Binaries
 - Types of binaries
 - Visual, astrometric, eclipsing, spectroscopic
 - Detached, semi-detached, contact
 - Mass determination
 - Hidden companions
- The Interstellar Medium
 - Extinction and Reddening
 - The 21cm hydrogen line
 - Interstellar Clouds
 - Absorption Nebulae
 - Reflection Nebulae
 - Emission Nebulae

Very metal poor stars - HE 1327-2326

$$[\text{Fe}/\text{H}] = -5.2$$

300,000 times less Iron than the Sun

$$\text{Yet, } [\text{C}/\text{H}] = -1.0$$

Only 10 times less Carbon

Very metal poor stars - HE 1327-2326

$$[\text{Fe}/\text{H}] = -5.2$$

300,000 times less Iron than the Sun

Yet, $[\text{C}/\text{H}] = -1.0$

Only 10 times less Carbon

Why?

Very metal poor stars - HE 1327-2326

$$[\text{Fe}/\text{H}] = -5.2$$

300,000 times less Iron than the Sun

Yet, $[\text{C}/\text{H}] = -1.0$

Only 10 times less Carbon

Why?

*There must be a delay between
Carbon production and Iron production
in the Galaxy*

Core-Collapse (Type II) Supernova

The Iron is in the core,
that undergoes neutronization

The iron is (almost) completely lost!!

***Ejecta of Type II SN is
carbon-rich but iron poor.***

Onion-layer structure

Core-Collapse (Type II) Supernova

The Iron is in the core,
that undergoes neutronization

The iron is (almost) completely lost!!

***Ejecta of Type II SN is
carbon-rich but iron poor.***

*Most of the iron in the Galaxy comes
from **Type Ia Supernovae***

Onion-layer structure

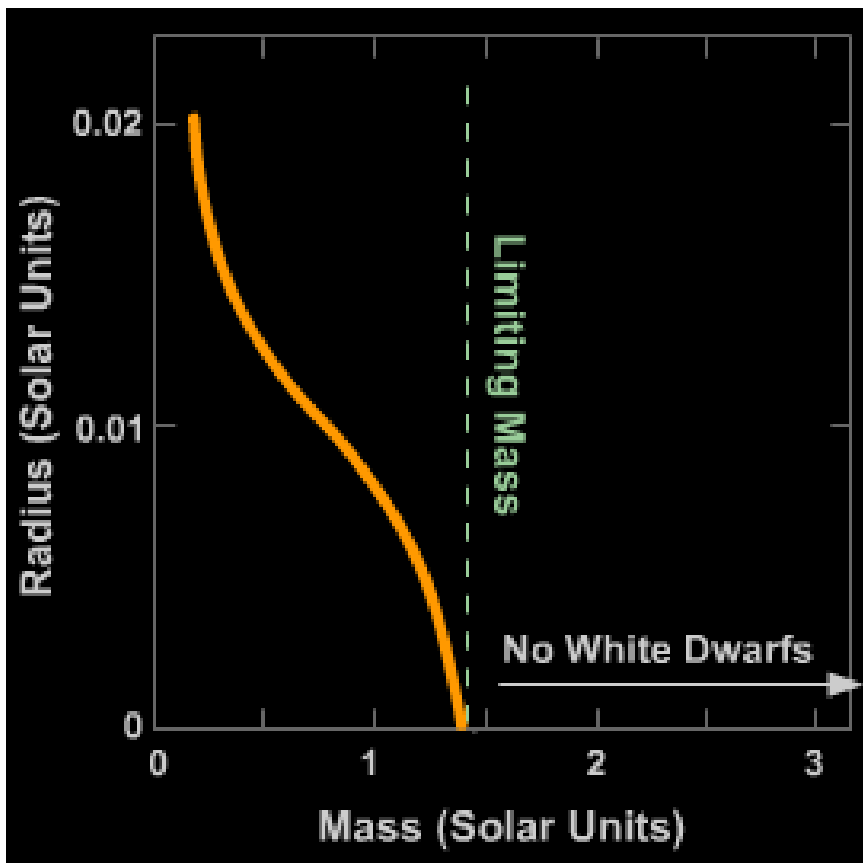

The other Supernovae

Supernovae Type Ia (White dwarf binary Supernovae)

White dwarf + Ordinary star

Steady and slow accretion onto a degenerate C-O white dwarf below the

Chandrasekhar limit

Mass-Radius relationship for degenerate matter.

Beyond $1.4 M_{\odot}$, electron degeneracy cannot hold against gravity

The other Supernovae

Supernovae Type Ia (White dwarf binary Supernovae)

White dwarf + Ordinary star

Chandrasekhar limit

The other Supernovae

Supernovae type Ia (White dwarf binary Supernovae)

White dwarf + Ordinary star

When the limit is achieved, the degenerate core implodes and achieves **carbon fusion** temperatures

This deflagrates a thermonuclear flame.

Carbon Detonation

The other Supernovae

Supernovae type Ia (White dwarf binary Supernovae)

White dwarf + Ordinary star

When the limit is achieved, the degenerate core implodes and achieves **carbon fusion** temperatures

This deflagrates a thermonuclear flame.

Carbon Detonation

So powerful that **no remnant** is left.

If the **Black Hole** is
gravity's ultimate victory,

the **Carbon detonation** is
pressure's ultimate victory!

The other Supernovae

Supernovae Type II - **Core collapse of a massive star** **INSTANTANEOUS (10 Myr)**

Supernovae Type Ia - **White dwarf binary** **GOTTA WAIT SOME BILLION YRS**

A galaxy is first enriched in alpha elements (from Type II SN)

Iron comes later (from Type Ia SN)

SN Ia as standard candles

Both SNIa and SNII detonate when the core reaches the Chandrasekhar limit

So they both have the same energy - 10^{51} erg

Why is SNIa a standard candle, and SNII is not?

SN Ia as standard candles

Both SNIa and SNII detonate when the core reaches the Chandrasekhar limit

So they both have the same energy - 10^{51} erg

Why is SNIa a standard candle, and SNII is not?

The envelope!!

SNII progenitor has a huge envelope that scatters some of the light

SNIa progenitor is a naked core

Binary and multiple stars

Most stars are found in multiple systems
Isolated (single) stars like the Sun are rare!!

Types of Binary stars

Visual Binaries
Astrometric binaries

WIDE

Spectroscopic binaries
Eclipsing binaries

CLOSE

Wide
(long orbital periods – 100-1000 yrs)

Close
(short orbital periods – days)

Visual Binary

We see the two stars

Astrometric Binary

One of the stars is too faint to be seen
But the visible star wobbles

Eclipsing Binary

The two stars periodically eclipse each other

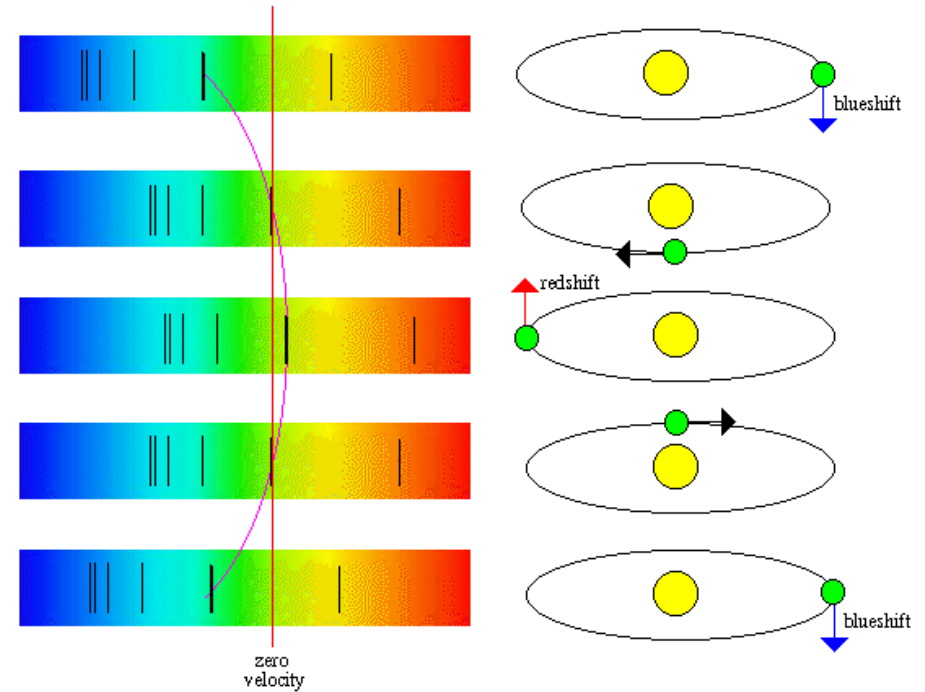

Copyright © 2005 Pearson Prentice Hall, Inc.

Spectroscopic Binary

Spectroscopic Binary

A spectroscopic binary is where there is evidence of orbital motion in the spectral features due to the Doppler effect

The Doppler effect

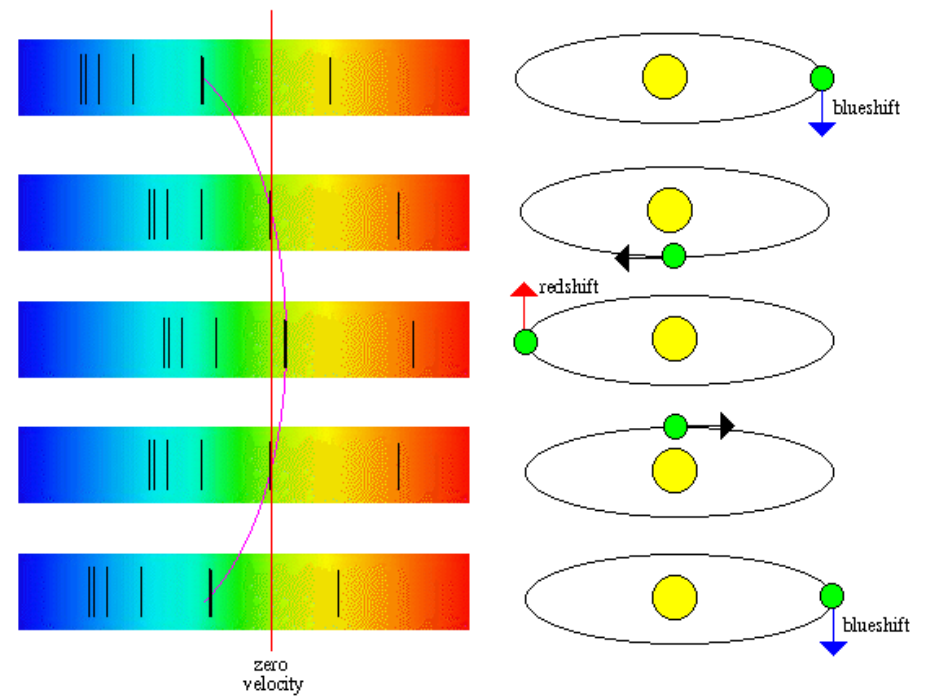

Change in wavelength caused by the motion of the source

Spectroscopic Binary

A spectroscopic binary is where there is evidence of orbital motion in the spectral features due to the Doppler effect

Observed Spectrum

Mass determination by evolutionary tracks

Measure a star's
luminosity and temperature,
compare with
model evolutionary tracks

Errors in luminosity, temperature

Plus, models are *not* perfect

Can easily add up to a large error in mass

Mass determination by orbits

$$F = - \frac{G M m}{r^2}$$

Alpha Centauri Masses

By orbital solution	1.105 +/- 0.007, 0.934 +/- 0.006
By evolutionary tracks	1.13 +/- 0.01, 0.89 +/- 0.05

← 10x more accurate

Classification by interaction

Roche Lobe

Gravitational region of influence

Lagrange Point

Equilibrium point where the gravity from both stars cancel each other

Hidden Companions

Hidden = Low Luminosity

Cygnus X1

Blue star orbiting an unseen object

From the orbit, the compact object must have a mass of **8 Msun**

Too massive to be a white dwarf or neutron star.

It's a Black Hole!!

The compact object emits **X-rays** from a region smaller than 0.1AU

Accretion disk around the black hole!!

Friction heats up the gas to **1 million K**
Very hot stuff emits X-rays

Stellar Extinction

A foggy day

Stellar Extinction

A foggy day

A foggy place

Starlight is extincted by dust in the Interstellar Medium

Stellar Extinction

Starlight is extinguished by dust in
the interstellar medium

$$V - M_V = -5 + 5 \log d$$

Stellar Extinction

Starlight is extinguished by dust in the interstellar medium

$$V - M_V = -5 + 5 \log d + A_V$$

Stellar Extinction

Starlight is extinguished by dust in the interstellar medium

$$V - M_V = -5 + 5 \log d + A_V$$

Extinction!!

Stellar Extinction

Starlight is extinguished by dust in the interstellar medium

$$V - M_V = -5 + 5 \log d + A_V$$

Extinction!!

Just as in a foggy day,
the amount of
extinction depends on the *distance*

Reddening

The extinction depends on wavelength
Dust absorbs and scatters more blue light than red light

Starlight is “de-blued”

When not totally extinguished,
the star will look *reddened*

We speak of a *color excess*, $E(B-V)$

$$B-V = (B-V)_0 + E(B-V)$$

$$A_V = R_V E(B-V)$$

$$R_V \sim 3.1$$

Avoid extinction. Go infrared.

Dust more efficiently absorbs and scatters bluer wavelengths

A lot of extinction in ultraviolet and optical

Little extinction in infrared

Go to infrared to see through the dust!!

B, V, I

B V I
image

B, I, K

B I K
image

Avoid extinction. Go infrared.

Visible • WFPC2

Infrared • NICMOS

Trapezium Cluster • Orion Nebula
WFPC2 • Hubble Space Telescope • NICMOS

NASA and K. Luhman (Harvard-Smithsonian Center for Astrophysics) • STScI-PRC00-19

Wow, infrared is great!
What if we used even longer wavelengths?

Can we try radio?

The 21cm (1420 MHz) line of neutral hydrogen (HI)

Spin transition

Nothing is more abundant than neutral hydrogen
Plus, it's RADIO! Unstoppable!

This 21cm radiation should be pervading the Galaxy

A map of the Galaxy in the 21cm HI line

Interstellar Nebulae

Interstellar clouds can be referred to as absorption (dark), reflection or emission nebulae

Absorption Nebula

Reflection Nebula

Emission Nebula

Interstellar Nebulae

Interstellar clouds can be referred to as absorption (dark), reflection or emission nebulae

Absorption Nebula

Absorption Nebulae

A lot of gas and dust
simply blocking light

Interstellar Nebulae

Reflection Nebulae

Physically the same as dark nebulae,
but **illuminated** by nearby stars.
The dust shines by reflected light

Usually blue (why?)

Interstellar Nebulae

Reflection Nebulae

Physically the same as dark nebulae, but **illuminated** by nearby stars.
The dust shines by reflected light

Usually blue (why?)

1. **Illuminated by blue/white stars**
2. Same reason why the sky is blue
Blue is better scattered than red

Interstellar Nebulae

Absorption and reflection nebulae are the same object

Reddening and Extinction

Absorption

Reflection

Reflection + Absorption

Interstellar Nebulae

Emission Nebulae

Glow by their own light

Illuminated by nearby OB stars,
very hot stars that emit ionizing radiation

When the electrons recombine, they cascade
emitting light in all the atom's discrete set of
wavelengths

Interstellar Nebulae

Emission Nebulae

Glow by their own light

Usually red (why?)

Illuminated by nearby OB stars,
very hot stars that emit ionizing radiation

When the electrons recombine, they cascade
emitting light in all the atom's discrete set of
wavelengths

Interstellar Nebulae

Emission Nebulae

Hydrogen emission in the **6563 Å** line (H α)

Glow by their own light

Usually red (why?)

Illuminated by nearby OB stars,
very hot stars that emit ionizing radiation

When the electrons recombine, they cascade
emitting light in all the atom's discrete set of
wavelengths

Interstellar Nebulae

Emission Nebulae

Kirchhoff's laws

Hydrogen emission in the **6563 Å** line (H α)

HII Regions

Emission Nebulae are also called HII Regions
HII for Ionized Hydrogen
(Neutral Hydrogen is HI)

Emission nebulae

Emission Nebulae are red because of hydrogen emission in H-alpha
Can you tell then why are Supernovae Remnants and Planetary Nebulae so colorful?

Crab Nebula
Supernova Remnant

Ring Nebula
Planetary Nebula

Emission nebulae

Emission Nebulae are red because of hydrogen emission in H-alpha
Can you tell then why are Supernovae Remnants and Planetary Nebulae so colorful?

Crab Nebula
Supernova Remnant

Ring Nebula
Planetary Nebula

Chemically enriched !!
Not just hydrogen...

Spectrum of the Crab Nebula

Prominent
Silicon line
 (redder than **H-alpha**)
 and **Oxygen line**
 (green)

Emission, Reflection, and Absorption in the same nebula

Trifid Nebula

An entanglement of nebulae...

The Antares-Rho Ophiuchi Region

Can you sort what you see?

An entanglement of nebulae...

The Antares-Rho Ophiuchi Region

Can you sort what you see?
